Introduction

Digital light processing technology (DLP) employs a light source and millions of tiny mirrors to produce vibrant, high-resolution images for a wide variety of industries and applications. It is critical to maintain an optimum operating temperature during use to prevent degradation of the digital light processor device. Active cooling solutions utilizing Peltier cooling modules can provide DLP thermal management in a wide range of applications.

Background

DLP technology is based on optical micro-electro-mechanical systems (MEMS) technology. It uses a grid of microscopic, highly-reflective aluminum mirrors placed on a semiconductor chip known as a digital micromirror device (DMD). The DMD receives electrical input through electronic control units (ECU) individually positioned adjacent to each micromirror and produces optical output via spatial light distribution. Separate control of each micromirror optimizes performance, resulting in a highly efficient, reliable, and high-speed device. A DLP chip uses millions of micromirrors to project sharp, crisp images with extremely high feature resolution and vibrant colors. DLP technology works with a variety of light sources, including high-powered LEDs and lasers, depending on the specific application.

DLP technology is used in the following three major applications:

Automotive

The automotive industry uses DLP technology in smart headlights and head-up displays (HUD). Smart headlights automatically manage the direction of the high beams, adjusting them away from oncoming traffic or into the direction of a turn so they illuminate and enhance the driver’s viewable area. The light from smart headlights travels farther, providing a longer viewpoint and more time for the driver to safely respond to hazards ahead. Head-up displays project images, which may include travel speed or directions from a GPS system, onto the windshield within the driver’s field of view. This allows the driver to remain focused on the road ahead rather than looking down at the dashboard. An additional safety feature in HUD may be enhanced signage recognition with display on the windshield.

Head-up displays (HUD) is one of the major applications using DLP technology
Display and projection

In display and projection applications, DLP technology uses two chip sizes. Pico chipsets are used for compact and ultra-mobile applications, delivering excellent image quality for devices including smartphones, tablets, virtual and augmented reality headsets and glasses, gaming accessories, medical devices, and elevator signage. Smart home applications such as thermostats, lighting, appliance displays, and entertainment systems can also operate using these pico chipsets. Larger displays use standard chipsets and include applications such as laser TVs, large-scale digital signage in airports and sporting arenas, and educational tools like classroom multimedia devices where vivid, high-resolution images are needed.

Advanced light control

The third application is advanced light control, where DLP technology offers high-resolution light patterns, extremely fast pattern rates, and highly reliable pixel control. Stereolithographic 3D printing is an additive-manufacturing technique in which material is deposited, one layer at a time, to build an object; DLP technology exposes each complete layer to light to cure the photosensitive polymers. Digital lithography, used in the manufacture of printed circuit boards, relies on DLP to expose the photosensitive materials without the need for contact masking. Spectroscopic analysis units can use DLP chips as wavelength selectors, eliminating the need for a linear-array detector and improving the efficiency of the chemical analysis. Additional applications exist in the medical, food, and agricultural arenas. DLP chips are available in light wavelengths in the visible, ultraviolet, and near-infrared spectrums, depending on the specific application.

Thermal Challenges

Design engineers can experience a variety of thermal challenges when implementing DLP technology, including thermal noise, SWaP (size, weight, and power) constraints, lack of airflow, and outgassing. DLP systems also inherently generate heat during operation that needs to be efficiently dissipated to maintain proper operation.

DLP systems utilize a highly temperature-sensitive semiconductor chip as the base for the DMD. DMD systems operate efficiently from 0 – 70 °C. DMD performance is extremely robust over this relatively large operating temperature range. However, there is a direct correlation between extreme temperature conditions and performance degradation. As a result, operating and storage temperature limits are imposed on DMDs.

Most DLP systems operate in high-heat environments. Temperatures in smart headlights, for example, can reach as high as 110°C due to a combination of external environmental conditions, heat generated by adjacent electronics, and heat generated by the DLP laser itself. In addition, many applications require packing more electronics into compact spaces to meet size and weight requirements, which further increases the heat flux density and complicates thermal issues. For example, the more information a HUD unit displays, the higher power it requires. A higher-powered unit will generate more heat, raising the operating temperature of the system.

In addition to operating in tight spaces, automotive and consumer electronics need to be lighter and more efficient, which requires a DLP cooling solution that is just as compact and efficient. Space constraints can negatively impact airflow, resulting in reduced performance of the thermal management solution such as heat sinks. This is often found in compact smart headlight compartments where air does not always flow consistently in one direction, lowering
the effect of the heat sink. Consistent airflow ensures proper heat dissipation, as does proper selection of a thermal solution that accounts for all application variables.

Additionally, it is important to consider environmental issues. In DLP applications, outgassing must be avoided at all costs as it can coat the light source or system optics and degrade performance over time. Creating protective exteriors to prevent moisture, condensation, and the ingress of other outside contaminants is critical in protecting sensitive electronics.

**Thermal Solutions**

There are two methods for heat dissipation in DLP components. Passive cooling using thermal interface materials is an efficient process that uses conduction to dissipate thermal energy. Passive cooling systems have no moving parts, making them ultra-reliable. However, they cannot cool below the ambient temperature and are unable to solve the thermal issues inside DLP devices. Active thermoelectric cooling, on the other hand, uses a Peltier cooler and a heat sink with a fan or blower to provide efficient spot cooling of DLPs, which keeps the device well within its specified operating temperature range to ensure peak performance and image quality.

Active cooling systems—like Peltier cooling modules—manage the heat-sensitive DMD’s temperature by creating a temperature differential. A Peltier cooling module can lower the temperature by as much as 40°C from the hot-side temperature of the heat exchanger. The Peltier cooler module can be installed so that it comes in direct contact with the DLP, or a cold block can be created to cool the DLP. When power is applied to the Peltier cooling module, it absorbs heat from DLP sensor or cold block and pumps thru the module and into a hot side heat dissipation mechanism, which typically is a heat sink and fan. It is important to ensure that the hot-side heat sink does not saturate, which would allow heat to flow back into the device. Optimizing the Peltier cooling module for a high coefficient of performance (COP) is critical, however. Temperature sensing with closed-loop feedback and control may be necessary as well. Even though Peltier cooling modules cost more than passive cooling, they are necessary in high temperature applications.

**Laird Thermal Solutions for DLPs**

Laird Thermal Systems has expertise in designing and implementing Peltier thermal management solutions, with proficiency in mating heat exchangers to maximize heat transfer most efficiently, no matter the airflow characteristics. Laird Thermal Systems offers both
standard and custom design solutions to eliminate thermal noise and meet application SWaP (size, weight, and power) requirements. Peltier cooling modules also eliminate outgassing, as the proprietary thermal interface materials feature extremely low outgas properties.

HiTemp ET Series Peltier modules are designed for applications where the ambient temperature exceeds the maximum operating temperature of the sensitive electronic requiring cooling. The Peltier module features an enhanced construction that prevents performance-degrading copper diffusion, which is common in standard-grade Peltier modules operating in temperature environments exceeding 80°C. The HiTemp ET Series protects critical DLP electronic devices and provides active cooling for applications operating in temperatures ranging from 80°C to 150°C with precise temperature control up to 0.01°C. The modules offer reliable solid-state construction, long life operational and a compact form factor that fits into most DLP applications.

The HiTemp ET Series is available in more than 50 models with a wide range of heat-pumping capacities, geometric form factors, and various input voltages to cover the wide range of DLP design requirements. Heat pumping capacities range from 1.5 over 100 Watts in form factors as small as 6 mm x 6 mm to 40 x 40 mm square.

The HiTemp ET Series is the ideal cooling solution for DLP electronic devices.

Selecting the right thermal solution for a particular application can be a long and difficult process for a thermal engineer, one that requires many technological and financial trade-offs. In order to speed-up and simplify this process, Laird Thermal Systems developed the Thermal Wizard™ to serve as a virtual thermal management assistant so that thermal decisions can be made faster and more accurately. The Thermal Wizard does the heavy lifting, sorting through the data and calculating the performance, leaving the decisions to the designer. The Thermal Wizard simulates cooling applications to help select thermoelectric modules, thermoelectric assemblies, or liquid cooling systems. The Thermal Wizard is available at https://www.lairdthermal.com/thermal-wizard/thermal-wizard-home-qc-requirements
Conclusion
DLP technology is used for applications ranging from smart automotive headlights and vehicle head-up displays to projection and advanced light control. Heat fluctuations within the devices can lead to degradation of performance, loss of accuracy, and reduced image resolution. Use of active cooling solutions with Peltier modules can provide the necessary protection to keep sensitive electronics below their maximum operation temperatures. Laird Thermal Systems offers both standard and custom design solutions that meet DLP technology requirements.

About Laird Thermal Systems
Laird Thermal Systems develops thermal management solutions for demanding applications across global medical, industrial, transportation and telecommunications markets. We manufacture one of the most diverse product portfolios in the industry ranging from active thermoelectric components and assemblies to temperature controllers and liquid cooling systems. Our engineers use advanced thermal modeling and management techniques to solve complex heat and temperature control problems. By offering a broad range of design, prototyping and in-house testing capabilities, we partner closely with our customers across the entire product development lifecycle to reduce risk and accelerate their time-to-market. Our global manufacturing and support resources help customers maximize productivity, uptime, performance and product quality. Laird Thermal Systems is the optimum choice for standard or custom thermal solutions. Learn more by visiting www.lairdthermal.com.
